CyberX

FUN INTERNET SAFETY

A College Project Report on Cybersecurity Awareness

Project Type: Responsive, Interactive Educational Website

Technology: HTML5, CSS3 and JavaScript

Prepared as project documentation

1. Abstract

CyberX is a mobile-friendly cybersecurity awareness website that introduces users to practical online safety habits. It presents key topics through small interactive activities rather than long blocks of technical text. The site is implemented as a self-contained static webpage using HTML, CSS and JavaScript.

2. Problem Statement

Internet users may encounter phishing messages, weak or reused passwords, malicious software and unsafe sharing practices. Beginners benefit from approachable explanations and low-risk practice activities that demonstrate how to identify warning signs and adopt safer habits.

3. Aim and Objectives

Aim: To develop an engaging website that improves basic cybersecurity awareness.

- Explain password hygiene and provide a practice-only strength indicator.
- Demonstrate warning signs in a sample phishing message.
- Introduce viruses, spyware and ransomware.
- Assess basic knowledge with a scored quiz.
- Encourage safer habits using a checklist and progress indicator.
- Provide a simple response sequence for suspected account or device compromise.

4. Scope

The project is intended for learning and awareness. It does not scan devices, connect to accounts, collect credentials, send information to a server, or replace professional security tools. The password meter is a simple educational heuristic and should not be treated as a formal password audit.

5. Technologies Used

- HTML5: page structure, content and accessible form controls.
- CSS3: responsive layout, neon colour palette, cards, animations and mobile styling.
- JavaScript: password feedback, phishing game scoring, flip cards, quiz logic and checklist progress.
- PDF documentation: project overview, design, features and testing notes.

6. Main Modules

Password practice: A text input updates a visual meter based on length and character variety. The interface warns users not to enter real passwords.

Phishing game: Three suspicious parts of a mock message can be tapped. Each selection reveals an explanation and updates the score.

Malware cards: Flip cards explain viruses, spyware and ransomware, alongside basic defensive practices.

Cyber-smart quiz: Four multiple-choice questions provide immediate feedback and a final score.

Safety shield: A checklist tracks selected habits and calculates a percentage of checked items.

Incident response: A short sequence recommends stopping interaction, securing accounts from a trusted device, contacting the provider, checking the device and reporting the incident.

7. Design and Usability

The visual design uses a dark purple background with cyan, pink, yellow and green accents to create a memorable learning experience. Content is divided into numbered sections. Responsive CSS supports narrow mobile screens as well as larger displays. Buttons and interactive cards are sized for touch use, and live feedback areas announce changes to assistive technologies.

8. How to Run

- Save or extract the project files into one folder.
- Open index.html in a modern browser. A web server and package installation are not required.
- For a shareable online link, upload the files to a static hosting service or publish the repository with GitHub Pages.
- See README.md for the GitHub Pages publishing steps.

9. Testing Checklist

- Password meter changes as sample text is entered and clears when the input is empty.
- Each of the three phishing flags can be selected once; the reset button clears the game.
- Each malware card flips by click, Enter or Space.
- Quiz answers show correct-answer highlighting, feedback and score; the quiz can restart.
- Safety checklist percentage updates when boxes are checked or unchecked.
- Page remains usable at phone and desktop widths.

10. Limitations and Future Enhancements

The password score is deliberately basic and does not measure real-world password entropy or check for breached credentials. The project does not include authentication, a database, server-side logging, malware scanning or automated threat intelligence. Future work could add multilingual content, a larger question bank, accessibility testing, and educator-facing lesson materials while preserving privacy.

11. Conclusion

CyberX demonstrates how a static website can communicate core cybersecurity concepts through interaction and immediate feedback. It provides a foundation for a college-level awareness project and can be hosted online without a backend or external dependencies.

General security guidance: use official service websites, keep software updated, use unique passwords, enable multi-factor authentication and maintain backups.
